

AN5012 Application note

Analog-to-digital audio conversion example using STM32L4 Series microcontroller peripherals

Introduction

The purpose of this application note is to provide an analog-to-digital audio conversion example using the STM32L4 Series microcontroller peripherals (OPAMP, ADC and the Full-Speed USB).

This example uses the ADC dedicated features to improve the conversion resolution and to automatically detect a programmable threshold level.

Note that the values provided in this application note are for reference only, measured in a laboratory under typical conditions (unless otherwise specified) and not tested in production.

1 The principle of an audio signal capture

1.1 Audio signal characteristics

The human auditory system is responsive to sounds in the frequency range of 20 Hz to 20 kHz as long as the intensity lies above the frequency dependent "threshold of hearing".

The audible intensity range is approximately 120 dB which represents the range between the rustle of leaves and the boom of an aircraft take-off.

Although any sampling frequency above 40 kHz would be adequate to capture the full range of audible frequencies, a widely used sampling rate is 44.1 kHz, which is from the historical need to the synchronize audio with video data. The "CD quality" refers to 44.1 kHz sampled audio digitized to a 16-bit word length.

The microphone converts the acoustic sound pressure into voltage regarding its own specifications, for example refer to the STM-MP33AB01 analog MEMS microphone available on www.st.com. The microphone has a signal to noise ratio of 63 dB at 94 dBSPL (sound pressure level) and its sensitivity is -38 dBV at 94 dBSPL. Its acoustic overload point is reached at 125 dBSPL and its power consumption is 250 uA with a supply voltage of 2.2 volts.

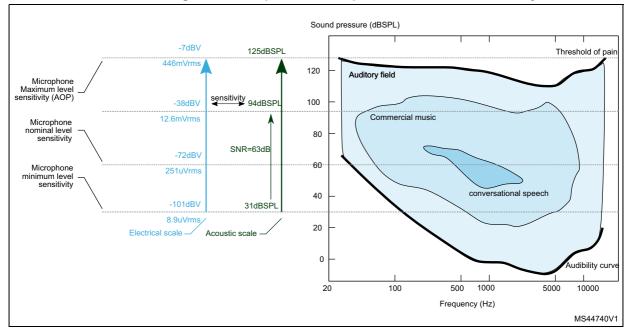

Figure 1. Microphone sound pressure level and sensitivity

6/38 DocID030334 Rev 1

Analog to Digital Converter (ADC) operating mode 2

Principle 2.1

The STM32L4 ADC peripheral is used to convert an external analog signal (voltage) into digital values for further processing in the digital domain. The ADC peripheral is a 12 bits successive approximation converter (SAR ADC) with additional oversampling hardware. Figure 2 represents the well-known ADC behavior:

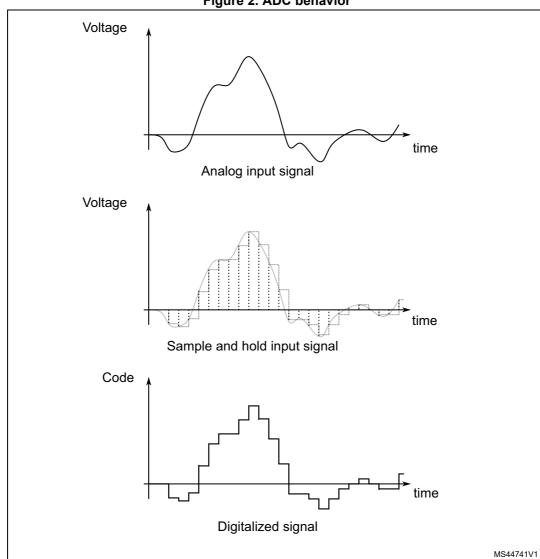

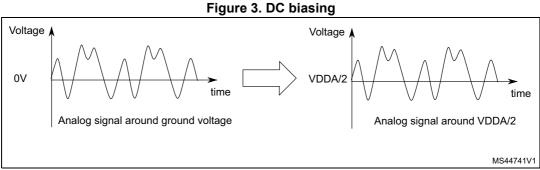

Figure 2. ADC behavior

2.2 STM32L4 ADC electrical circuitry network

The STM32L4 SAR ADC has a fixed input architecture which can be single-end or differential. If the application is using an analog microphone, a signal scaling with few external components is required.

2.3 DC adapting network

The STM32L4 ADC converts the input analog signal in voltage range 0 V to 1.62 V/3.6 V (VDDA supply). Because the microphone audio signal is centered on ground, a specific electrical schematic is required to adapt the common voltage mode from 0 V to VDDA/2, as shown in *Figure 3* and *Figure 4*.

This signal adaptation is performed using the following schematic (high-pass filter):

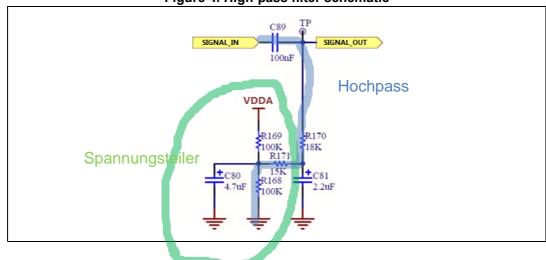

Figure 4. High-pass filter schematic

577

2.4 Gain of the pre-amplifier stage

The output level of the analog microphone is very small regarding the resolution of the ADC converter. The signal must be amplified correctly to fit with the input range of the converter. Here below a comparison is done of the analog signal level with and without gain.

Without amplification, the acquired audio signal corresponding to 60 dBSPL sound pressure has an equivalent electrical level (RMS) of 251 uV or -72 dBV (see *Figure 1*).

The less significant bit (LSB) represents the minimum voltage that can be converted. Using the STM32L4 ADC with the lowest voltage for VDDA (1.65 V), its value can be calculated using the following formula:

Note: This LSB level is greater than 251 uV coming from the microphone.

The signal coming from the microphone must be amplified using either an external amplifier or the STM32L4 build-in OPAMP.

With an amplification of 24 dB (internal amplification with the OPAMP peripheral), the amplified electrical signal has an amplitude of 4 mV or -48 dBV:

ADC input signal = Microphone signal x Amplifier gain =
$$(251.10^{-6})$$
 x $10^{(24/20)}$ = (251.10^{-6}) x $15.85 = 4.10^{-3} = 4$ mV or 20 x $log10(4.10^{-3}) = -48$ dBV

Using the STM32L4 ADC with VDDA = 3.3 V and an over sampling ratio of 64, *Table 1* shows the ADC output amplitude obtained in the numeric domain (ADC LSB = VDDA/2^{Nb bits ADC}).

Audio Source Parameter ADC output level Gain **ADC** input level Dynamic range dBSPL dΒ FS with OSR =64 Units mVrms dB mVpp Value 60 4 11.31 24 898 59

Table 1. ADC dynamic range

The dynamic range is the ratio between the maximum and the minimum signal level (0 lsb is the minimum level while the maximum level depends on the gain in the acquisition path).

2.5 Anti-alias filter

Because the ADC converter is sampling and holding the input signal to avoid any folding/aliasing effect, the signal should not change during the sample acquisition duration and a simple low-pass filter (last stage) may be added in order to attenuate the signal above the Nyquist–Shannon sampling frequency (Fs_{ADC}/2).

In this application example, a first order low-pass filter is used with R=5 k Ω and C=1 nF. Its cut-off frequency (Fc) is equal to 31.8 kHz and the attenuation at 20 kHz (calculated) is -1.44 dB.

2.6 Schematic using an STM32L4 internal OPAMP

Figure 5 shows the interface schematic between the MEMS microphone and the operational amplifier.

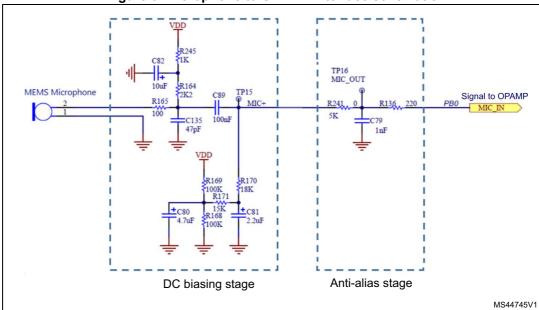

Figure 5. Microphone to OPAMP interface schematic

Note:

The signal quality provided by the microphone is very sensitive to noise on its biasing voltage: a clean signal should be used to power the bias voltage.

3 Implementation with the STM32L4 Series microcontroller

3.1 Overview of the project architecture

The purpose of this application is to capture an audio signal from an analog microphone and convert it into the numeric domain using the STM32L4 OPAMP and ADC peripherals. In our example, the USB peripheral (USB audio device) is also used and has an access to the converted data (share DMA memory) in order to stream the audio content to a computer.

The build-in ADC analog watchdog is also used to monitor the audio level which can be useful in voice detection applications.

The signal analysis can be performed easily with the host computer using a programming language for a scientific computing like octave with the Large Time/Frequency Analysis Toolbox (LTFAT).

The environment is based on the following material: NUCLEO-L476RG + CCA02M1 boards (see *Figure 6*).

The microphone and the associated circuity: biasing and anti-alias filter components are placed on an external Arduino shield prototype board or a custom Arduino shield printed circuit board.

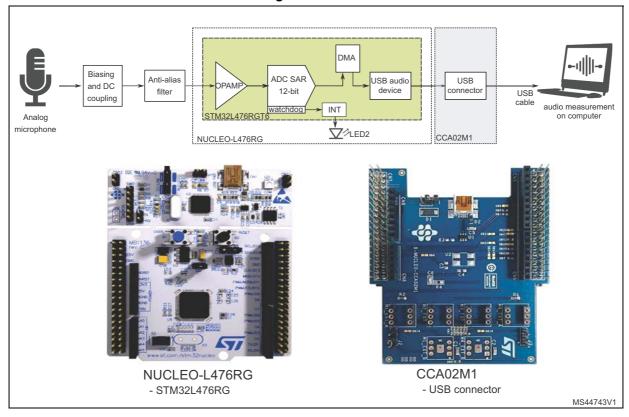

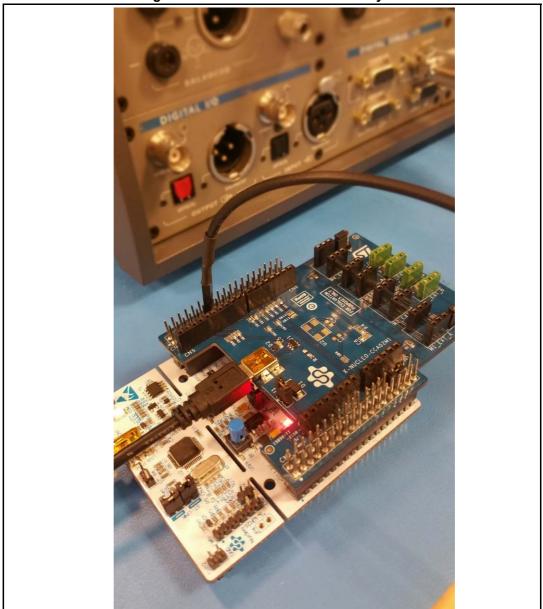

Figure 6. Hardware overview

Figure 7 presents the stack board with the audio analyzer.

12/38 DocID030334 Rev 1

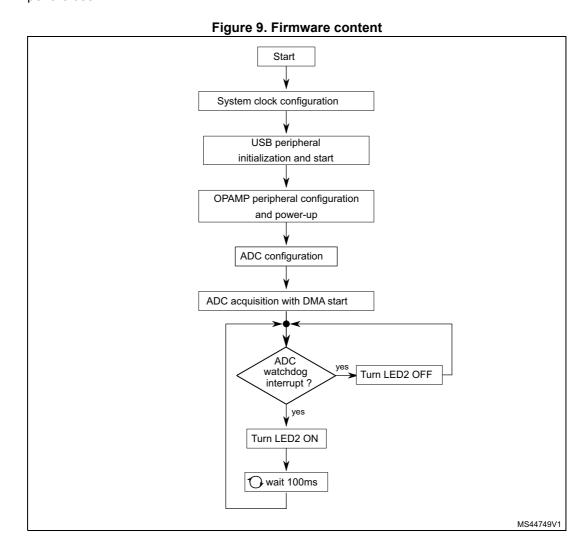

The USB audio device is available under Windows 7 operating system as a stereo recording device, as shown on *Figure 8*.

Figure 8. Microphone recording

3.2 Architecture of the firmware

Figure 9 represents the firmware content. After initializing the system clocks and the microcontroller peripherals, a continuous loop is monitoring the ADC watchdog interrupt. When the ADC watchdog occurs, the LED2 toggles from OFF state to ON state to be visible per the user.

There is a second firmware mechanism to exchange data between the ADC and the USB device using the DMA, as shown in *Figure 10*.

ADC/DMA circular memory **USB 2.0 FS** ADC sample 1st half block peripheral memory 48 samples Stereo buffer USB interface 2nd half block R 2x48 samples 48 samples ADC/DMA callback event ADC watchdog status → 48 samples repeated MS44748V1

Figure 10. DMA data exchange between ADC and US peripherals

3.3 Architecture of the clock tree

3.3.1 Architecture presentation

The following architecture has be retained to be compatible with the USB and the ADC sampling rate needs. The MSI RC clock is set to 48 MHz to be directly used by the USB device peripheral. The main PLL is programmed at 76.8 MHz to the ADC1 peripheral clock.

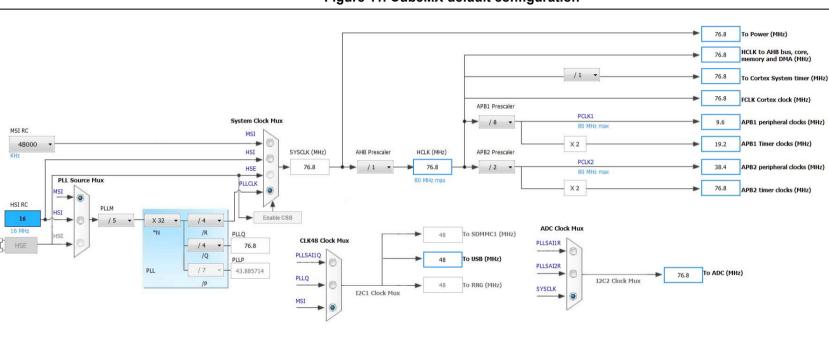

Figure 11. CubeMX default configuration

3.3.2 Clocks constraints and relationship

When the ADC resolution is set to 12 bits: 12.5 clock cycles must be added to the sampling time which is programmable from 2.5 to 640.5 clock cycles. Finally the sampling rate of the ADC varies from 15 to 653 clock cycles. If the user expects a standard audio rate (48 kHz) which is available in the USB audio device standard. *Table 2* displays the main ADC clock frequency range regarding the oversampling ratio (OSR) and the number of ADC clock cycles. The gray highlighted values show the compatibility with the ADC peripheral (its maximum frequency is 80 MHz).

Table 2. ADC clock frequency range versus OSR and clock cycle (48 kHz)

ADC clock frequency (kHz)				
Total clock cycles	OSR=1	OSR=16	OSR=32	OSR=64
15	720	11520	23040	46080
19	912	14592	29184	58368
25	1200	19200	38400	76800
37	1776	28416	56832	113664
60	2880	46080	92160	184320
105	5040	80640	161280	322560
260	12480	199680	399360	798720
653	31344	501504	1003008	2006016

The following setup has been selected to continue the implementation of this application note:

- ADC SAMPLETIME =12.5 CYCLES
- ADC_OVERSAMPLING_RATIO (OSR) = 64
- FADC= SYSCLK = 76.8 MHz

3.3.3 USB peripheral clocking

The USB device in our firmware application has a timing constraint which requires 1 ms buffer size. The USB audio device sample rate is set to 48 kHz and it has 2 channels (interlaced data): 2 x 48 samples or 1 x 96 buffer size has to be sent every 1 ms.

The ADC/DMA data exchange mechanism (see *Figure 12*) is used to transfer the audio data from the ADC peripheral to the USB device. The ADC DMA memory size is 96 samples: every half and full callback completed samples $1\rightarrow48$ and $49\rightarrow96$ are transferred. The ADC acquires one channel at the 48 kHz rate which is associated to the left USB audio channel, the second audio channel (right) is filled with the ADC analog watchdog status value (0 or 1).

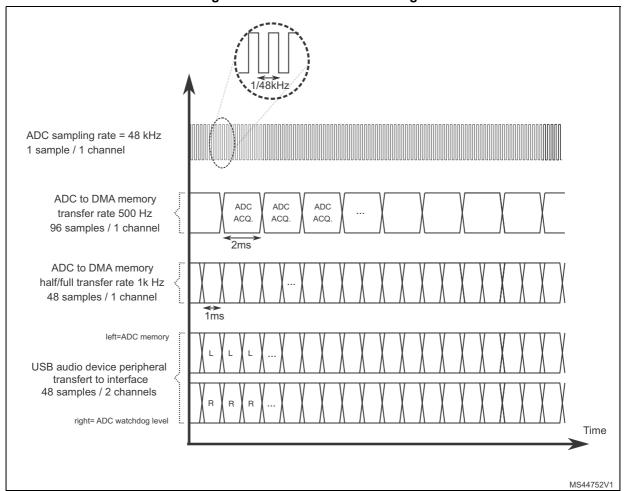

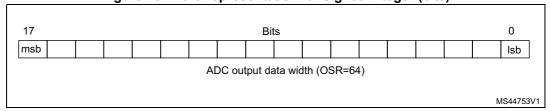

Figure 12. ADC/DMA data exchange mechanism

18/38 DocID030334 Rev 1

3.4 Data format (numeric domain)

The native row data available at the ADC (12bits) output is unsigned binary words represented between from the code 0x0 to the code 4095 (hexadecimal format). When using an oversampling ratio of x64, the built-in accumulator is delivering data in the following range: from 0x0 to 0x3FFC0 (hex format) which requires 18 bits to be represented.

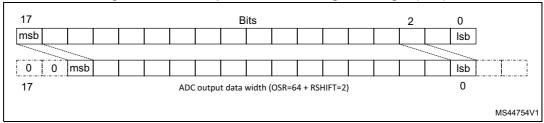

Figure 13. Word representation: unsigned integer (bits)

The USB peripheral data format is signed 16 bits (int16_t) which is corresponding to a decimal range between -32768 and +32767. A format transformation is required to guarantee a lossless transfer between the peripherals (ADC → USB audio device). This transformation requires several steps:

 Usage of the ADC embedded feature to automatically shift and obtain output data in integer 16-bits wide.

Figure 14. Word representation: unsigned integer (bits)

- Final step to convert the unsigned word into signed word using the following formula:
 - USB_Peripheral_{word} = ADC_Peripheral_{word} 2^(word_size-1) where word size= 16

Figure 15. Word representation: signed integer (bits)

Using a 1kHz sinus wave with an amplitude higher than the input range of the ADC, the input level can be saturated in order to measure the maximum and minimum level in the numeric domain and also verify any wrapping effect due to binary signed words.

Figure 16 shows an audio signal example with a saturated sinus at the ADC input, OSR = 64, RS = 2, ADC continous acquisition.

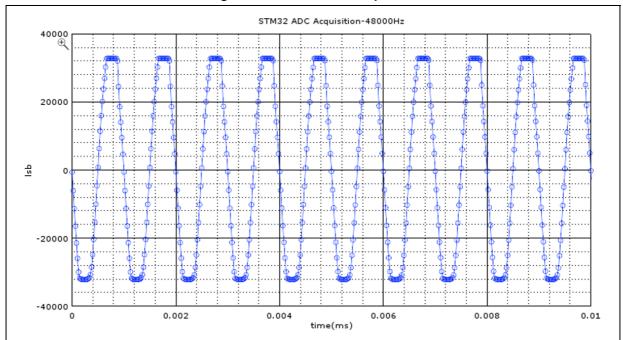

Figure 16. STM32 ADC acquisition - 48000 Hz

Note: The figure shows a saturated signal to highlight the full dynamic of the digital path from -32768 lsb to +32767 lsb.

AN5012 Application

4 Application

A basic application covered with this application note is the voice activity detection with a programmable threshold level. Once the detection occurs, the device can start the audio recording which will be stored for an embedded signal processing or can immediately transfer the audio data to another peripheral or system.

4.1 Simple voice detection using ADC watchdog feature

The STM32 ADC embeds an analog watchdog which is a very useful feature to detect a certain threshold or window level. The STM32 ADC watchdog has 2 programmable thresholds (low and high) which are defining a normal operation window. Outside of this window, the watchdog interrupt callback appears.

Figure 17 shows both the audio signal and the analog watchdog interrupt signal embedded in the USB audio frame (left channel is the audio from ADC and the right channel is the watchdog interrupt '0' for status <<0>> or '16384' for status <<1>>).

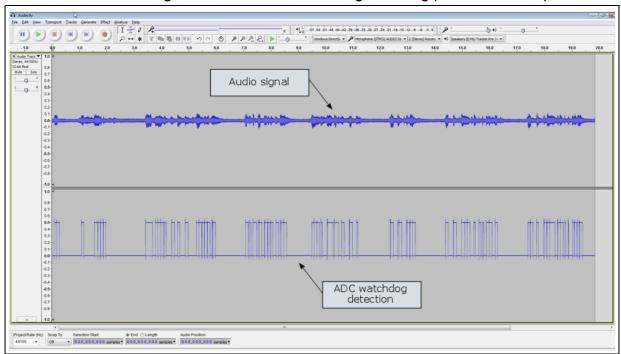

Figure 17. Audio and ADC analog watchdog (threshold +/- 128)

The programmable threshold must be chosen regarding the product application and its environment. If it is very noisy, a large watchdog window is preferable while a quiet ambient noise allows to set a reduced window size.

Application AN5012

For this application note, a window width of +/-128 lsb has been selected for a full spread of 4096 lsb (see *Figure 18*). Note that the watchdog detection is an internal feature of the ADC and the windows size is based on the acquisition resolution of the ADC itself (12 bits in our case).

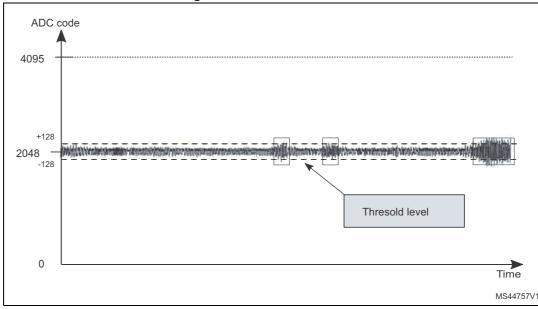

Figure 18. ADC code window

With the material setup using the external per-amplifier gain (42 dB) and the analog microphone (ST-MP33AB01), the peak value corresponding to a 60 dBSPL sound pressure level is:

- ADC analog input = 89.4 mVpp
- 6 dB margin for the threshold detection
- With VDDA=3.3V, the peak code calculated is:

Peak_{code} =
$$(0.0894/2) \times (2^{12}/3.3) \times 2 = 111 \sim 128 \text{ lsb}$$

This threshold calculation should be verified using a repetitive audio pattern and improving the efficiency of the detection system.

Note:

In real conditions, the DC offset provided by the microphones may vary, and it will probably cause false detections if it is not properly canceled or calibrated.

5 Audio measurements definition

5.1 Offset measurement

The offset measurement is the mean value of the output signal (numeric domain). Normally, the system should deliver an output signal around the mid-scale of the system. In this application, the mid-scale values for the ADC output is 0x7FFF (unsigned 16 bits) and for the USB audio device it is 0x0000 (signed 16 bits). When a signal is acquired, the user can compare the signal output average with the mid-scale of the system (ADC or USB)

5.2 Frequency response measurement

This measurement is used to define the frequency range of the audio system. Most of the time, the amplitude of the output level at 1 kHz is used as a reference which is compared to the measured amplitude. Concretely, the amplitude of the output signal is measured with a list a frequencies (20 Hz→20 kHz) and the attenuation in dB is calculated versus the reference (1 kHz amplitude). An audio system with a flat frequency (+/- 1dB) does not alter the audio signal and its content which will guarantee a good audio rendering.

5.3 Dynamic-range measurement

The dynamic-range measurement is defined by the ratio in dB between the maximum output level and its noise level (minimum output signal).

5.4 Total Harmonic Distortion

The THD represents the linearity performances of the application. During this test, a single tone is applied to the input of audio system. Mathematically, the harmonics are extracted of the input fundamental and the ratio is calculated in dB or percentage between the main tone and its distortion (harmonics).

6 Signal acquisition measurements

The measurement conditions are:

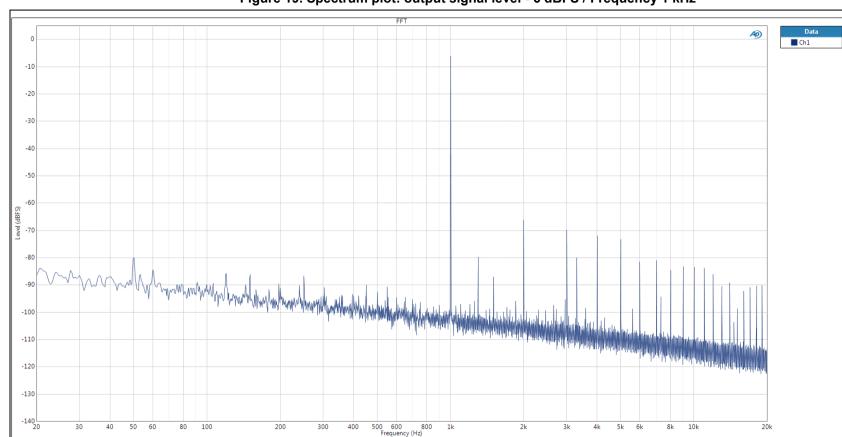

- Signal generator (Audio Precision APx 526)
- VDDA = 3.3 V
- OPAMP GAIN = 24 dB
- ADC OSR = 64

The following figures show the audio measurements done with the STM32L4 Series device.

ENOB	8.6	Bits

6.7 Power consumption

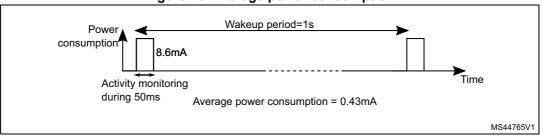

During the audio measurements, the power consumption of the STM32L476 Series device has also been measured. The total of the power consumption is 8.6 mA without the USB peripheral when the signal acquisition is performed continuously.

Figure 25. Power consumption

The signal acquisition duration can be limited to 50 ms and the MCU can be set in sleep mode until the next wakeup interrupt. Thanks to this mechanism, the power consumption is reduced to 0.43 mA (average value), as shown on *Figure 26*.

Figure 26. Average power consumption

57

7 Measurement conclusions

A signal acquisition application from an analog microphone can be done in a very simple way using the STM32L476 Series microcontroller with its embedded OPAMP and ADC peripherals and the dedicated ADC features (oversampling ratio, watchdog).

The global performance is interesting for a simple consumer application to detect, store and post-process an audio signal from an analog microphone.

The OPAMP is increasing the noise level at the input of the ADC but is also introducing some non-linearity.
